BAB I

DESKRIPSI MASALAH

Gambar 1.1. *Rush Hour Puzzle*

(Sumber: <https://www.thinkfun.com/en-US/products/educational-games/rush-hour-76582>)

Rush Hour adalah sebuah permainan puzzle logika berbasis grid yang menantang pemain untuk menggeser kendaraan di dalam sebuah kotak (biasanya berukuran 6x6) agar mobil utama (biasanya berwarna merah) dapat keluar dari kemacetan melalui pintu keluar di sisi papan. Setiap kendaraan hanya bisa bergerak lurus ke depan atau ke belakang sesuai dengan orientasinya (horizontal atau vertikal), dan tidak dapat berputar. Tujuan utama dari permainan ini adalah memindahkan mobil merah ke pintu keluar dengan jumlah langkah seminimal mungkin.

Komponen penting dari permainan Rush Hour terdiri dari:

1. Papan – Papan merupakan tempat permainan dimainkan. Papan terdiri atas cell, yaitu sebuah singular point dari papan. Sebuah piece akan menempati cell-cell pada papan. Ketika permainan dimulai, semua piece telah diletakkan di dalam papan dengan konfigurasi tertentu berupa lokasi piece dan orientasi, antara horizontal atau vertikal. Hanya primary piece yang dapat digerakkan keluar papan melewati pintu keluar. Piece yang bukan primary piece tidak dapat digerakkan keluar papan. Papan memiliki satu pintu keluar yang pasti berada di dinding papan dan sejajar dengan orientasi primary piece.

2. Piece – Piece adalah sebuah kendaraan di dalam papan. Setiap piece memiliki posisi, ukuran, dan orientasi. Orientasi sebuah piece hanya dapat berupa horizontal atau vertikal–tidak mungkin diagonal. Piece dapat memiliki beragam ukuran, yaitu jumlah cell yang ditempati oleh piece. Secara standar, variasi ukuran sebuah piece adalah 2-piece (menempati 2 cell) atau 3-piece (menempati 3 cell). Suatu piece tidak dapat digerakkan melewati/menembus piece yang lain.
3. Primary Piece – Primary piece adalah kendaraan utama yang harus dikeluarkan dari papan (biasanya berwarna merah). Hanya boleh terdapat satu primary piece.
4. Pintu Keluar – Pintu keluar adalah tempat primary piece dapat digerakkan keluar untuk menyelesaikan permainan
5. Gerakan — Gerakan yang dimaksudkan adalah pergeseran piece di dalam permainan. Piece hanya dapat bergerak/bergeser lurus sesuai orientasinya (atas-bawah jika vertikal dan kiri-kanan jika horizontal). Suatu piece tidak dapat digerakkan melewati/menembus piece yang lain.

Alur program:

1. **[INPUT]** Konfigurasi permainan/test case dalam format .txt yang berisi:
 - a. Dimensi Papan (A x B)
 - b. Banyak piece yang **BUKAN** *primary piece* (N)
 - c. Konfigurasi papan dengan pintu keluar dilambangkan **X** dan *primary piece* dilambangkan **P**. Cell kosong dilambangkan dengan titik (*period*) ‘.’

Contoh file txt:

```
6 6
12
A A B . . F
. . B C D F
G P P C D F K
G H . I I I
G H J . . .
L L J M M .
```

2. **[INPUT]** algoritma pathfinding yang digunakan
3. **[INPUT]** heuristic yang digunakan (bonus)
4. **[OUTPUT]** Banyaknya **gerakan** yang diperiksa (banyak ‘node’ yang dikunjungi)
5. **[OUTPUT]** Waktu eksekusi program
6. **[OUTPUT]** Konfigurasi papan pada setiap tahap pergerakan. (‘animasi’)

BAB II

TEORI SINGKAT

2.1. *Uniform Cost Search (UCS)*

Uniform Cost Search merupakan algoritme penelusuran graf yang mencari jalur ber-biaya total paling kecil dari simpul awal ke simpul tujuan. Termasuk golongan uninformed search, UCS tidak memakai informasi jarak ke goal; ia hanya memprioritaskan jalur dengan akumulasi biaya terendah sejauh ini.

Algoritme ini mengevaluasi setiap simpul n dengan fungsi:

$$f(n) = g(n)$$

di mana $g(n)$ adalah biaya dari start hingga n . Simpul dengan nilai $f(n)$ paling kecil selalu diambil dari *priority queue* untuk diperluas. Jika kemudian ditemukan rute yang lebih murah menuju simpul yang sama, rute yang lebih mahal dibuang.

Selama semua bobot langkah bernilai non-negatif, UCS menjamin solusi optimal. Metode ini cocok untuk persoalan di mana biaya minimum lebih penting daripada kecepatan, misalnya penentuan rute, penjadwalan, atau puzzle berbobot. Namun, tanpa bantuan heuristik, UCS dapat menjadi lambat karena harus menelusuri seluruh jalur termurah satu per satu sebelum mencoba jalur lain.

2.2. *Greedy Best First Search (GBFS)*

Greedy Best-First Search adalah algoritme *informed search* yang mengandalkan heuristik untuk “menyerbu” ke arah goal secepat mungkin. Pada setiap langkah ia memilih simpul dengan estimasi jarak ke tujuan terkecil, tanpa memedulikan biaya yang telah dikeluarkan untuk mencapainya.

Fungsi evaluasinya adalah:

$$f(n) = h(n)$$

di mana $h(n)$ merupakan taksiran jarak dari n ke goal. Strategi yang hanya melihat ke depan ini bisa sangat cepat jika heuristiknya akurat, tetapi karena mengabaikan biaya lampau, jalur yang dipilih tidak dijamin paling murah. GBFS mudah terperangkap pada optimum lokal atau jalur buntu yang tampak dekat secara heuristik tetapi mahal secara nyata.

Algoritma ini berguna ketika diperlukan respons cepat dan optimalitas bukan prioritas utama, misalnya navigasi awal, keputusan sementara, atau aplikasi real-time dengan batas waktu ketat.

2.3 A-star Algorithm (A-star)

A* Search menggabungkan kekuatan UCS dan GBFS dengan menyeimbangkan biaya nyata dan estimasi sisa biaya. Setiap simpul dievaluasi menggunakan:

$$f(n) = g(n) + h(n)$$

dengan $g(n)$ = biaya dari start ke n dan $h(n)$ = perkiraan biaya dari n ke goal.

Dengan selalu memperluas simpul ber- $f(n)$ terendah, A* memprioritaskan jalur yang sejauh ini murah sekaligus menjanjikan. Apabila heuristik $h(n)$ admissible (tidak melebihi-lebihkan) dan konsisten, A* pasti menemukan jalur optimal.

Keunggulannya adalah mampu mencapai solusi terbaik lebih efisien daripada UCS karena ruang pencarian disempitkan oleh heuristik. Meski demikian, pada ruang pencarian sangat besar atau heuristik kurang akurat, kebutuhan memori dan waktu A* tetap bisa tinggi.

BAB III

METODE PENYELESAIAN

Permainan Rush Hour dapat dimodelkan sebagai penelusuran pada graf ruang-keadaan:

- Simpul : mewakili satu konfigurasi papan (posisi semua kendaraan).
- Sisi : mewakili satu gerakan legal, yaitu menggeser sebuah mobil searah orientasinya.

Dengan pemodelan ini, algoritma pencarian jalur seperti Uniform Cost Search (UCS), Greedy Best-First Search (GBFS), dan A* bisa digunakan untuk menemukan solusi.

Target penelusuran adalah keadaan akhir, konfigurasi di mana mobil utama berhasil keluar. Solusi sendiri berupa rangkaian keadaan dari posisi awal hingga akhir, yang sekaligus menunjukkan urutan langkah penyelesaian. Untuk lebih detailnya sebagai berikut:

3.1. *Heuristics*

Heuristik adalah fungsi $h(n)$ yang mengestimasi jarak (atau biaya) dari simpul n ke simpul tujuan tanpa melebihi biaya sebenarnya (admissible). Heuristik utama yang pertama kali diimplementasi pada program ini adalah Manhattan:

$$h_{\text{Manhattan}}(n) = |x_{\text{dep}} - x_K|$$

di mana x_{dep} adalah koordinat kolom ujung depan primary piece pada konfigurasi n , dan x_K adalah kolom pintu keluar (pada baris yang sama). Karena setiap langkah menggeser satu petak dihitung sebagai satu langkah, Manhattan distance tidak pernah melebihi jumlah langkah minimal yang diperlukan untuk mencapai pintu keluar, sehingga admissible.

3.2. *Mapping Heuristics dengan Algoritma Pathfinding*

Setelah heuristik ditentukan, fungsi evaluasi $f(n)$ untuk masing-masing algoritma ditetapkan sebagai berikut:

- Uniform Cost Search (UCS)

$$f(n) = g(n)$$

Dengan $g(n)$ adalah jumlah langkah yang telah dilakukan dari status awal sampai n . Karena $h(n)=0$, UCS akan mengeksplorasi simpul berdasarkan $g(n)$ terkecil, berperilaku identik dengan BFS pada graf berbiaya seragam.

- Greedy Best-First Search (GBFS)

$$f(n) = h(n)$$

GBFS hanya menggunakan estimasi heuristik tanpa mempertimbangkan biaya aktual. Simpul yang dieksplorasi adalah yang terlihat paling dekat ke tujuan menurut $h(n)$, sehingga—meski cepat—GBFS tidak menjamin solusi optimal.

- A* Search

$$f(n) = g(n) + h(n)$$

Gabungan komponen biaya aktual (g) dan estimasi heuristik (h) memastikan A* menjelajah secara efisien sekaligus optimal, asalkan $h(n)$ admissible. Priority queue akan memproses simpul dengan $f(n)$ terendah, memotong cabang-cabang yang kurang menjanjikan dan mengurangi jumlah simpul yang dieksplorasi dibanding UCS.

Dengan pemetaan-pemetaan tersebut, setiap algoritma dapat dijalankan terpisah sesuai masukan pengguna, sehingga kita dapat membandingkan jumlah node yang diperiksa, waktu eksekusi, dan optimalitas solusi yang dihasilkan.

BAB IV

IMPLEMENTASI

4.1. Implementasi Program

Implementasi program dibagi menjadi beberapa sumber kode. Masing-masing sumber kode memiliki peran khusus untuk penyelesaian masalah. Pembagian sumber kode dilakukan untuk menyederhanakan masalah agar dapat lebih mudah dipahami. Berikut adalah kode sumber yang ada dalam implementasi program.

4.2. Kode Sumber

4.2.1. Model

4.2.1.1. Board.java

```
package com.java.model;

import com.java.exception.MoveBlockedException;
import java.util.*;

public class Board {
    private final int rows, cols;
    private final char[][] grid;
    private final Map<Character, Piece> pieces = new HashMap<>();
    private int exitRow = Integer.MIN_VALUE, exitCol = Integer.MIN_VALUE;

    public Board(int rows, int cols) {
        this.rows = rows;
        this.cols = cols;
        grid = new char[rows][cols];
        for (int r = 0; r < rows; r++)
            Arrays.fill(grid[r], '.');
    }

    public void setExit(int r, int c) {
        exitRow = r;
        exitCol = c;
    }

    public void parseCell(int r, int c, char ch) {
        if (ch == 'K') {
            setExit(r, c);
        } else if (Character.isLetter(ch)) {
            grid[r][c] = ch;
            if (!pieces.containsKey(ch)) {
                pieces.put(ch, new Piece(ch, r, c, 1, true, ch == 'P'));
            } else {
                Piece p = pieces.get(ch);
                int newSize = p.getSize() + 1;
                boolean horiz = (r == p.getRow());
                int anchorR = horiz ? p.getRow() : Math.min(p.getRow(), r);
            }
        }
    }
}
```

```

        int anchorC = horiz ? Math.min(p.getCol(), c) : p.getCol();

        };  
    }  
}
```

BAB V

IMPLEMENTASI BONUS

5.1. *Graphical User Interface (GUI)*

Dalam tugas kecil ini, kami berhasil mengimplementasikan bonus Graphical User Interface (GUI). Bonus ini dikerjakan dengan library JavaFX. GUI ini memiliki tiga window, yaitu menu utama, tampilan pencarian solusi (loading page) dan solusi.

Gambar 5.1.1. Main Menu GUI

Pada menu utama, pengguna dapat memilih konfigurasi puzzle dari file .txt. Konfigurasi yang tidak valid akan memunculkan pesan error. Pengguna juga dapat memilih algoritma yang akan digunakan dan heuristiknya (kalau heuristiknya memadai dengan algoritma yang dipilih). Setelah memilih algoritma dan puzzle, pengguna dapat memulai pencarian solusi.

Gambar 5.1.2. Loading GUI

Pencarian solusi akan dilakukan sementara GUI menampilkan pesan "Loading..." pada window tampilan pencarian solusi. Setelah selesai, GUI akan menampilkan window presentasi solusi.

Gambar 5.1.2. Result GUI

Hasil pencarian akan dipresentasikan dengan animasi sekuens status awal hingga status akhir. Animasi tersebut dapat diputar ulang menggunakan tombol ‘Replay Solution’. Presentasi hasil pencarian juga memberikan informasi berupa waktu pencarian, jumlah simpul, dan jumlah langkah. Untuk kembali ke menu utama, tombol ‘Back’ dapat ditekan.

5.2. Heuristik Alternatif

Dalam tugas kecil ini, kami berhasil mengimplementasikan bonus heuristik alternatif dengan mengimplementasikan tiga model heuristik yang dapat dipilih ketika menggunakan program, yaitu jumlah mobil yang menghalangi goal (EBlocking), Manhattan, dan pattern-recognition.

5.2.1. EBlocking.java

```
package com.java.searching.heuristic;

import com.java.model.Board;
import com.java.model.Piece;
import com.java.searching.State;

}

```

```
        this.ec = ec;
    }
}
```

5.3. Pathfinding Alternatif

Disini, program juga mengimplementasikan Algoritma pathfinding alternatif;

5.3.1. IDAStarSolver.java

Iterative Deepening A* (IDA* / IDA-Star) adalah varian dari algoritma A* yang memadukan ketelitian A* dengan konsumsi memori serendah *depth-first search*. Ia tetap *informed search*—menjadi “cerdas” berkat heuristik—tetapi menelusuri ruang-status secara bertahap memakai batas (*threshold*) yang kian diperlebar.

Dalam konteks Rush Hour, IDA* menjadi kompromi logis: ia mengekspansi jauh lebih sedikit simpul daripada UCS yang “buta”, tetap menemukan jalur minimum langkah layaknya A*, namun menahan kebutuhan memori agar tidak meledak saat puzzle semakin padat.

```
package com.java.searching;

import com.java.checker.PuzzleChecker;
import com.java.exception.InvalidConfigurationException;
import java.util.*;

public class IDAStarSolver implements SearchStrategy {
    public SolverResult solve(State start) {
        long t0 = System.currentTimeMillis();
        int threshold = start.heuristic();
        long nodes = 0;

        List<Move> path = new ArrayList<>();

        int iteration = 0;
        int maxIterations = 100; // Safety limit for extremely difficult puzzles

        while (iteration++ < maxIterations) {
            path.clear();

            Map<String, Integer> bestCost = new HashMap<>();

            Result result = new Result();
            result.nodesExpanded = nodes;

            boolean found = dfs(start, 0, threshold, path, bestCost, result);
            nodes = result.nodesExpanded;
        }
    }
}
```

```

        if (found) {
            return new SolverResult(path, nodes, System.currentTimeMillis() - t0);
        }

        if (result.nextThreshold == Integer.MAX_VALUE) {
            return new SolverResult(new ArrayList<>(), nodes, System.currentTimeMillis() -
t0);
        }

        threshold = result.nextThreshold;

        System.out.println("IDA* iteration " + iteration + ": increased threshold to " +
threshold);
    }

    // If we hit iteration limit, return best effort
    return new SolverResult(new ArrayList<>(), nodes, System.currentTimeMillis() - t0);
}

private static class Result {
    int nextThreshold = Integer.MAX_VALUE;
    long nodesExpanded = 0;
}

private boolean dfs(State state, int g, int threshold, List<Move> path,
    Map<String, Integer> bestCost, Result result) {
    result.nodesExpanded++;

    int h = state.heuristic();
    int f = g + h;

    // Prune if f-value exceeds threshold
    if (f > threshold) {
        result.nextThreshold = Math.min(result.nextThreshold, f);
        return false;
    }

    // Check for goal state
    boolean isGoal;
    try {
        isGoal = PuzzleChecker.checkSolved(state.getBoard());
    } catch (InvalidConfigurationException e) {
        isGoal = false;
    }

    if (isGoal) {
        return true;
    }

    String stateKey = state.toString();

    Integer previousCost = bestCost.get(stateKey);
    if (previousCost != null && previousCost <= g) {
        return false;
    }
}

```

```
bestCost.put(stateKey, g);

List<Move> successors = state.successors();
successors.sort(Comparator.comparingInt(move -> g + 1 + move.next.heuristic()));

// Try each successor
for (Move move : successors) {
    path.add(move);

    if (dfs(move.next, g + 1, threshold, path, bestCost, result)) {
        return true;
    }

    path.remove(path.size() - 1);
}

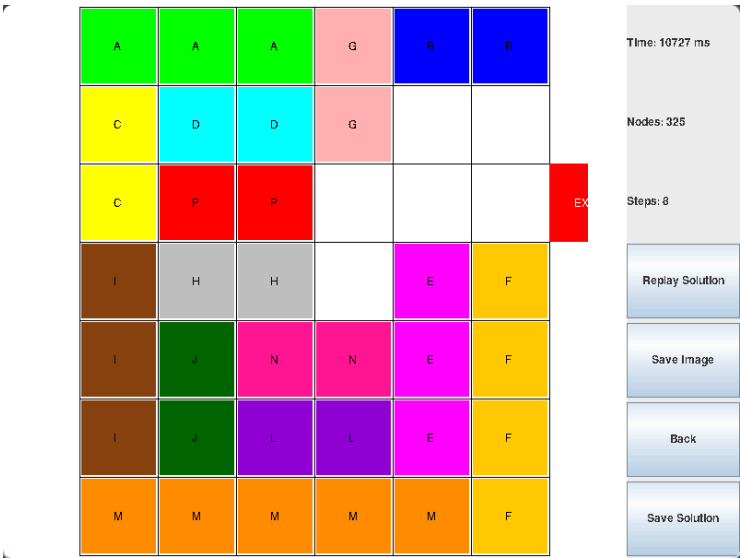

return false;
}
```

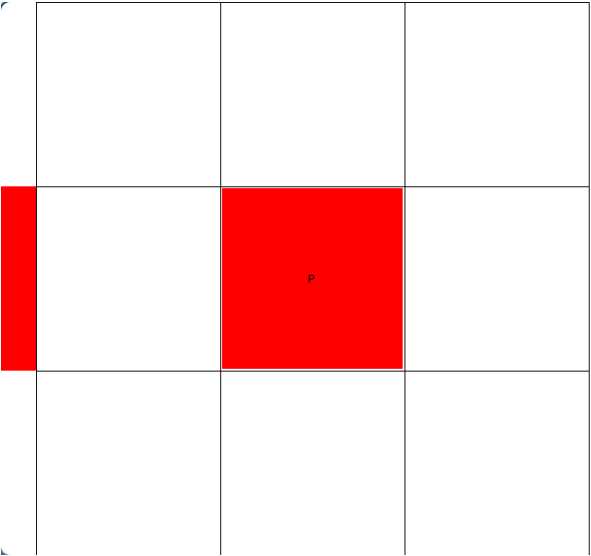

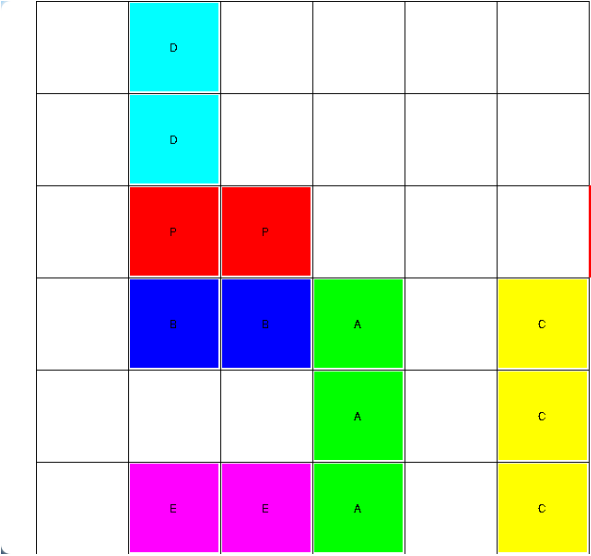

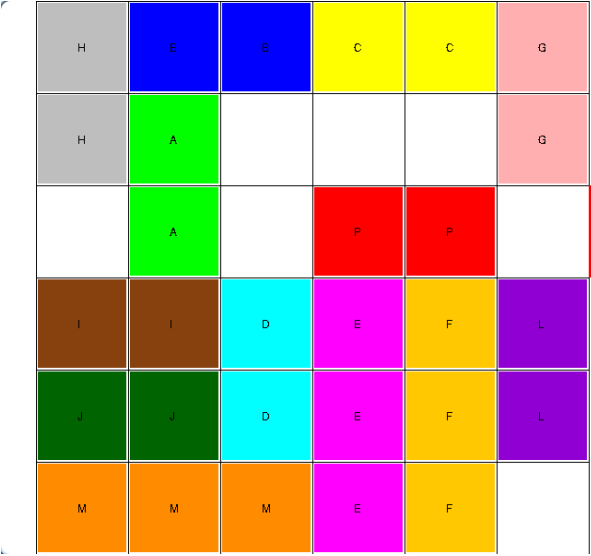

BAB VI

EKSPERIMEN DAN ANALISIS

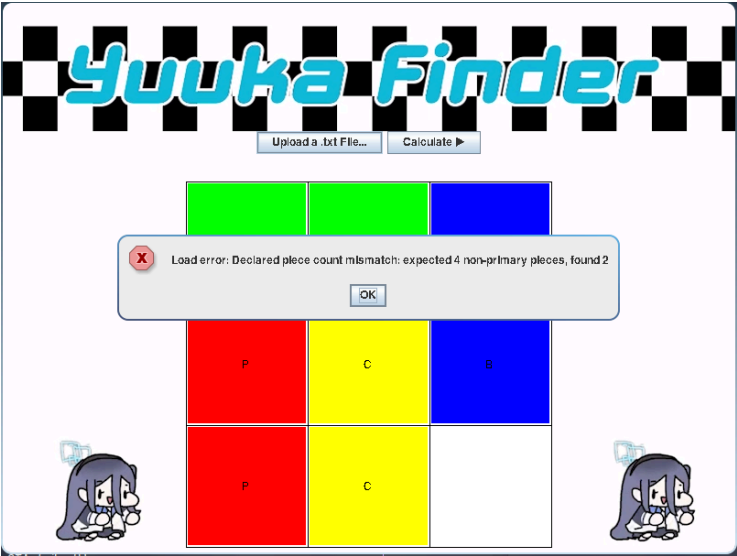

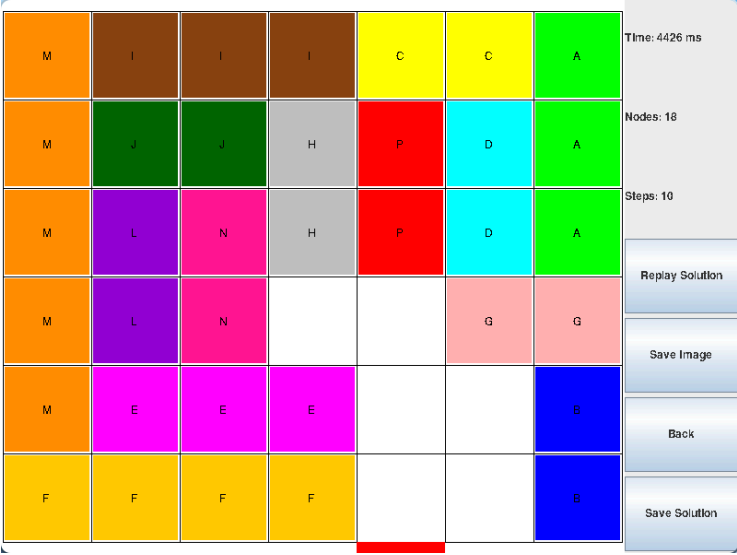

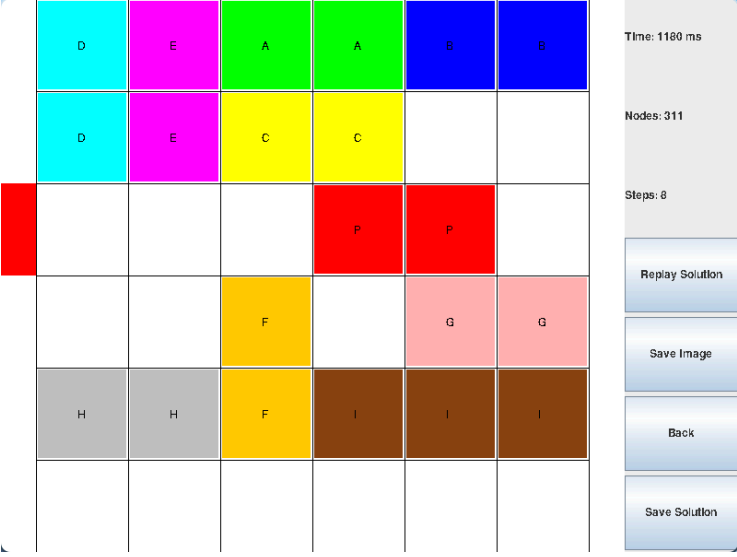

6.1. Pengujian Program

6.2. Analisis Hasil Percobaan

Analisis kompleksitas algoritma yang digunakan dibagi menjadi beberapa bagian. Hal ini dilakukan karena tipe pathfinding yang dipakai mempengaruhi hasil node, program search time, dan steps yang diambil. Pembagian analisis kompleksitas juga mempermudah dan membuat lebih jelas perhitungan kompleksitas algoritma yang digunakan. Berikut adalah analisis kompleksitas per bagian dari algoritma program yang dibuat:

6.2.1. Analisis Kompleksitas Algoritma UCS

Algoritma Uniform Cost Search mengekskansi simpul berdasarkan biaya kumulatif $g(n)$; dengan asumsi semua langkah bernilai non-negatif, perilakunya ekuivalen dengan Breadth-First Search ketika setiap gerakan memiliki bobot 1.

- Branching factor (b) : rata-rata banyaknya gerakan legal dari satu konfigurasi papan
- Kedalaman solusi (d) : jumlah langkah minimum sampai mobil utama keluar

Waktu terburuk: $O(b^d)$
Ruang Terburuk: $O(b^d)$

Karena UCS tidak memiliki petunjuk arah (*uninformed / blind-search*), ia mem-visit semua simpul pada kedalaman d sebelum beralih ke $d+1$. Pada puzzle Rush Hour dengan cabang luas atau solusi dalam, percobaan menunjukkan:

- jumlah simpul yang dibangkitkan jauh lebih banyak daripada A^*
- penggunaan memori melonjak (priority-queue berisi hampir seluruh frontier)

- waktu eksekusi menjadi paling lama di antara ketiga algoritma, walau solusi yang diperoleh tetap optimal.

6.2.2. Analisis Kompleksitas Algoritma GBFS

Greedy Best-First Search (GBFS) hanya melihat heuristik $h(n)$ di eksperimen, jumlah kendaraan yang memblokir pintu keluar—tanpa mempertimbangkan biaya lampau ($g(n)=0$ untuk semua n).

- Kedalaman solusi tercapai (m) : langkah pada jalur pertama yang dianggap menuju goal.

Waktu rata-rata: $O(b^m)$

Ruang rata-rata: $O(b^m)$

Nilai m sering kali $< d$, sehingga GBFS *praktis* jauh lebih cepat dan hemat memori daripada UCS. Hasil percobaan memperlihatkan:

- waktu penyelesaian tercepat, karena fokus langsung ke arah goal,
- panjang solusi cenderung lebih besar—kadang signifikan—dibanding UCS maupun A^* ,
- risiko terjebak pada jalur buntu meningkat jika heuristik kurang informatif atau tidak *admissible*.

Dengan kata lain, GBFS mengorbankan optimalitas demi efisiensi waktu, cocok untuk skenario di mana respon cepat lebih penting daripada jalur terpendek.

6.2.3. Analisis Kompleksitas Algoritma A^* (A-star)

Algoritma A^* (A-star) mengevaluasi simpul menggunakan fungsi $f(n) = g(n) + h(n)$ yang menyeimbangkan biaya nyata dan estimasi sisa biaya. Jika $h(n)$ *admissible* dan konsisten, A^* dijamin menemukan jalur optimal dengan eksplorasi yang lebih terarah.

Waktu terburuk: $O(b^d)$

Ruang terburuk: $O(b^d)$

Namun—berkat heuristik yang baik—jumlah simpul nyata yang dikunjungi jauh di bawah UCS. Dari percobaan:

- A^* selalu menghasilkan solusi dengan jumlah langkah minimum, setara UCS;
- penggunaan memori dan waktu rata-rata paling efisien di antara metode yang juga menjamin optimalitas

- performa tetap bergantung pada kualitas heuristik $h(n)$. Semakin dekat taksirannya ke jarak sesungguhnya, semakin kecil simpul yang diekspansi.

LAMPIRAN

Checklist Spesifikasi Program

Tabel 7.1. Tabel *checklist* spesifikasi program

No	Poin	Ya	Tidak
1	Program berhasil dikompilasi tanpa kesalahan	<input checked="" type="checkbox"/>	<input type="checkbox"/>
2	Program berhasil dijalankan	<input checked="" type="checkbox"/>	<input type="checkbox"/>
3	Solusi yang diberikan program benar dan mematuhi peraturan permainan	<input checked="" type="checkbox"/>	<input type="checkbox"/>
4	Program dapat membaca masukan berkas '.txt' dan menyimpan solusi berupa print board tahap-per-tahap dalam berkas '.txt'	<input checked="" type="checkbox"/>	<input type="checkbox"/>
5	[BONUS] Implementasi algoritma pathfinding alternatif	<input checked="" type="checkbox"/>	<input type="checkbox"/>
6	[BONUS] Implementasi 2 atau lebih heuristik alternatif	<input checked="" type="checkbox"/>	<input type="checkbox"/>
7	[BONUS] GUI	<input checked="" type="checkbox"/>	<input type="checkbox"/>
8	Program dan laporan dibuat (kelompok) sendiri	<input checked="" type="checkbox"/>	<input type="checkbox"/>
